Features

• Low Input Voltage of 1.6V over temperature
• Precision reference, error amplifier, and optocoupler in a single package
• Voltage Reference: 1.299V ±0.5% @ 25°C
  LIA135: ±1% @ -40°C to +85°C
  LIA136: ±1.5% @ -40°C to +110°C
• LIA136: Reduced dark current at high temperature
• Common Mode Transient Immunity:
  LIA135: 5V/ns
  LIA136: 20V/ns
• Simplified frequency compensation
• CTR 500% to 2000%
• Lowest optical offset current (ICE vs. VLED)

Applications

• Low Voltage Power Supply Feedback
• Isolated Power Supply Feedback
• AC-to DC Power Supplies
• DC-to-DC Converters

Description

The LIA135 and LIA136 are low voltage optically isolated error amplifiers with a precision programmable shunt reference combined into a single package capable of operating down to 1.6V. The optocoupler portion of the LIA135 / LIA136 comprises an infrared LED that is optically coupled to an NPN phototransistor providing a current transfer ratio from 500% to 2000%. Ensuring low voltage performance, the input voltage range of 1.6V to 10V is guaranteed over the operational temperature range.

The combination of features in the LIA135 / LIA136 are optimal for use in isolated AC-to-DC power supplies and DC-to-DC converters. The bias current for the shunt regulator does not pass through the LED, which eliminates bias-related optical current, giving the user the industry’s largest dynamic range (1000:1).

These devices are available in DIP and surface mount (SMT) packages.

Approvals

• UL Recognized Component: File # E76270
• CSA Certified Component: Certificate # 1305490

2. Functional Description

The LIA135 and LIA136 are optically isolated error amplifiers. Each comprises the three primary components necessary to implement feedback for an isolated power supply in a single package. These components are: an error amplifier; a voltage reference; and an optocoupler. The LIA135 and LIA136 are the functional equivalent of a 431 type precision shunt regulator and an optocoupler in the same package.

Understanding how the LIA135 and LIA136 function and are used is best understood by referencing the simplified application circuit shown in Figure 10: Typical Isolated Power Supply Using an Optical Feedback Error Amplifier. The function of the LIA135 / LIA136 is to sample the power supply output to be regulated, generate an error signal, and transmit the error signal across the isolation barrier to the power supply's control circuitry. Power for the input side circuits, consisting of an LED; a shunt regulator; and an error amplifier, is provided by the power supply's rectified secondary output (VOUT) via the series current limiting resistor (RLED) as shown in the application circuit.

Regulation of VOUT is made possible by applying a scaled sample of its voltage to pin FB, the error amplifier's non-inverting input. The error amplifier compares this scaled voltage (VFB) against an internal high accuracy reference voltage and generates an output which in turn sets the LED drive current.

As VOUT increases, the error amplifier's input voltage VFB will also increase. Ramping of VFB beyond the internal reference voltage causes the error amplifier to generate the LED drive current (IF) necessary to cause the optocoupler's NPN output transistor to conduct. Increasing the LED drive current results in an increase of the output transistor's collector current (IC) which in turn decreases the voltage seen at the collector (VC). This voltage is also commonly referred to as the Error Voltage (VE).

Likewise, a reduction of VOUT results in a lessening of IF causing VC to increase.

The power supply's control circuitry uses the error voltage presented by the optocoupler's output transistor to interpret the power needs of the secondary side load and to maintain regulation.
2.1 Input Side Biasing

Power for the LIA135 / LIA136 error amplifier, voltage reference, and optocoupler LED is applied to the LED pin through a current limiting resistor. Typically, this resistor’s voltage source is \( V_{\text{OUT}} \), the regulated power supply output. For very low voltage designs where \( V_{\text{OUT}} \) lacks sufficient headroom to bias the input circuitry, the resistor may be sourced from an auxiliary secondary winding on the transformer. When using the LIA135 / LIA136 this is an unlikely situation as these devices were designed specifically to be used for low voltage power supply applications. For all implementations, the minimum bias voltage at the LED pin is 1.6V.

There must be a current-limiting resistor (\( R_{\text{LED}} \)) in series with the LED pin to keep the current flow into the device and through the LED within their respective operating ranges for all expected supply output levels. Although the value of \( R_{\text{LED}} \) is determined in conjunction with the value of the phototransistor’s pull-up resistor \( R_C \), its minimum value is limited by the maximum allowed input current. See Section 3. Design Examples on page 10.

2.2 Supply Regulation

When connected as shown in the application circuit above and properly configured, the LIA135 / LIA136 will regulate \( V_{\text{OUT}} \) such that \( V_{\text{FB}} = V_{\text{REF}} \) (1.299V). To achieve this, the values of the voltage divider resistors, \( R_1 \) and \( R_2 \), must be set in the following manner:

\[
\frac{R_1}{R_2} = \frac{V_{\text{OUT}}}{V_{\text{REF}}} - 1
\]

Because \( V_{\text{OUT}} \) regulation occurs when \( V_{\text{FB}} = V_{\text{REF}} \) any change in bias current through \( R_2 \) at the desired regulated voltage level will cause a regulation error. As shown in the Electrical Characteristics table the error amplifier input at pin FB has an input bias current (\( I_{\text{IB}} \)) specification that reduces the current into \( R_2 \). (\( I_{\text{IB}} \) is always into pin FB). This error causes the regulated output voltage to increase which increases the current through \( R_1 \) by an amount equal to \( I_{\text{IB}} \), thereby restoring the current through \( R_2 \) to its original value.

Reducing the \( V_{\text{OUT}} \) error created by the input bias current to less than 1% is accomplished by setting the value of \( R_1 \) using the following formula:

\[
R_1 < \frac{V_{\text{OUT}}}{50\mu A}
\]

Where 50\( \mu \)A is 100 x \( I_{\text{IB}(\text{max})} \). This error can be reduced to less than 0.05% by setting the current to 1mA, i.e. 2000 x \( I_{\text{IB}(\text{max})} \).

2.3 Compensation

Frequency response of the converter can be optimized for the specific application by placing a compensation network between the COMP and FB pins of the LIA135 / LIA136. In a typical system with a low-bandwidth requirement, only a 0.1\( \mu \)F capacitor should be needed. For designs with more critical bandwidth requirements, measurements of the loop response must be made and compensation adjusted as necessary.

2.4 Optocoupler Output Transistor

The output phototransistor of the LIA135 / LIA136 provides the isolated and amplified feedback signal that represents the output of the converter. Typically, the collector of the phototransistor will be pulled up by a reference voltage provided by the power supply control chip and the emitter will be grounded.

The base of the LIA135 output transistor is not externally accessible. For the LIA136 however, the base is brought out at pin 2 enabling the user to extend the capabilities of the device beyond those of the LIA135. Placing a resistor from the base to the emitter extends the operational temperature range by shunting base current around the base-emitter junction thereby reducing dark current at elevated temperatures. Immunity to large common mode transients (CMTI) is enhanced by placing a capacitor parallel to the base-emitter resistor. This shunts transient currents around the base-emitter junction rather than having them amplified by the transistor.

When using the LIA136 the base-emitter resistor must be populated, otherwise the open base lead will pick up atmospheric electromagnetic signals converting them into noise components.

2.5 N/C Pins

The N/C (No Connect) pins have no internal connection.
3. Design Examples

There are two basic designs, one with a discrete resistor at the optocoupler output whose value can be selected by the designer and the other with a resistor integrated within the power supply's PWM controller IC whose value is fixed. Common to both design flows is setting up the feedback from the power supply output to the error amplifier input.

For the discrete optocoupler output resistor solution, the design flow is determining the value of R\text{LED} and then the optocoupler output resistor, R\text{C}. When the optocoupler output resistor value is preselected and fixed, the design procedure is reversed. In both cases the value of these two resistors is dependent on the other.

3.1 Error Amplifier Input Configuration

Regulation of the power supply's output voltage is accomplished by configuring the voltage divider network consisting of R\text{1} and R\text{2} to apply a voltage equal to the Reference Voltage (V\text{REF}) to FB, the feedback amplifier's input, when the supply's output is at it's desired potential.

For this example, the nominal value of the power supply output voltage is 1.8V. Because the LIA135 and LIA136 operate with an input voltage of 1.6V there is no requirement to provide an auxiliary transformer winding to bias the optical feedback circuitry.

To reduce regulation error caused by loss of bias current into pin FB, the current through R\text{1} must be set much greater than I\text{IB}, the leakage current into pin FB. Setting R\text{1} = 1kΩ, a convenient common value will ensure the current through R\text{1} will be much greater than I\text{IB}.

With R\text{1} = 1kΩ and setting R\text{2} = 2.61kΩ will fix the nominal supply output voltage to 1.797V, just slightly below the target value of 1.8V.

3.2 Discrete Optocoupler Output Resistor

The value of the optocoupler’s collector pull-up resistor (R\text{C}) and of the LED current-limiting resistor (R\text{LED}) must be determined together with respect to the input voltage range of the power supply's PWM device. Additionally, the operational range and performance characteristics of the LIA135 and LIA136 must be taken into account.

As an example, consider first that the minimum CTR of the LIA135 / LIA136 is 500%. Selection of R\text{LED} to set the minimum current through the LED (I\text{F}) to 1mA when the converter output (V\text{OUT}) is at it’s nominal value of 1.797V is as follows:

\[
R\text{LED} \leq \frac{V\text{OUT} - V\text{LED}(\text{min})}{I\text{F} + I\text{Q(max)}}
\]

\[
R\text{LED} \leq \frac{1.797V - 1.6V}{1mA + 100\mu A} = 0.197V/1.1mA = 179.09\Omega
\]

Using the nearest standard value that satisfies the relationship above sets R\text{LED} = 178Ω. Rearranging the terms and calculating for the LED current gives

\[
I\text{F} = \frac{1.797V - 1.6V}{R\text{LED}} = 100\mu A
\]

The value R\text{LED} = 178Ω selected above satisfies the minimum value of the LED resistor.

3.3 Integrated Optocoupler Output Resistor

Many times the collector pull-up resistor is integrated into the PWM controller IC and may be a current source rather than a resistive component.

The design methodology is similar to the external discrete pull-up resistor design but the LED current limiting resistor must be calculated starting from the pull-up at the optocoupler output transistor's collector.
4. Manufacturing Information

4.1 Moisture Sensitivity

All plastic encapsulated semiconductor packages are susceptible to moisture ingress. IXYS Integrated Circuits Division classified all of its plastic encapsulated devices for moisture sensitivity according to the latest version of the joint industry standard, IPC/JEDEC J-STD-020, in force at the time of product evaluation. We test all of our products to the maximum conditions set forth in the standard, and guarantee proper operation of our devices when handled according to the limitations and information in that standard as well as to any limitations set forth in the information or standards referenced below.

Failure to adhere to the warnings or limitations as established by the listed specifications could result in reduced product performance, reduction of operable life, and/or reduction of overall reliability.

This product carries a Moisture Sensitivity Level (MSL) rating as shown below, and should be handled according to the requirements of the latest version of the joint industry standard IPC/JEDEC J-STD-033.

<table>
<thead>
<tr>
<th>Device</th>
<th>Moisture Sensitivity Level (MSL) Rating</th>

</tbody>
</table>

4.2 ESD Sensitivity

This product is ESD Sensitive, and should be handled according to the industry standard JESD-625.

4.3 Soldering Profile

Provided in the table below is the Classification Temperature ($T_C$) of this product and the maximum dwell time the body temperature of this device may be above ($T_C - 5$)°C. The classification temperature sets the Maximum Body Temperature allowed for this device during lead-free reflow processes.

<table>
<thead>
<tr>
<th>Device</th>

<td>3</td>
</tr>
</tbody>
</table>

4.4 Board Wash

IXYS Integrated Circuits Division recommends the use of no-clean flux formulations. Board washing to reduce or remove flux residue following the solder reflow process is acceptable provided proper precautions are taken to prevent damage to the device. These precautions include but are not limited to: using a low pressure wash and providing a follow up bake cycle sufficient to remove any moisture trapped within the device due to the washing process. Due to the variability of the wash parameters used to clean the board, determination of the bake temperature and duration necessary to remove the moisture trapped within the package is the responsibility of the user (assembler). Cleaning or drying methods that employ ultrasonic energy may damage the device and should not be used. Additionally, the device must not be exposed to flux or solvents that are Chlorine- or Fluorine-based.
4.5 Mechanical Dimensions

4.5.1 LIA135 & LIA136 DIP Package

4.5.2 LIA135S & LIA136S SMT Package
4.5.3 LIA135STR & LIA136STR SMT Tape & Reel

**NOTES:**
1. Dimensions carry tolerances of EIA Standard 481-2
2. Tape complies with all “Notes” for constant dimensions listed on page 5 of EIA-481-2
